Compounds that are non-specific to any of the above-mentioned alpha2 subtypes, and compounds that are specific to certain alpha2 subtypes, are already known. For example, atipamezole is a non-specific alpha2 antagonist. Atipamezole has been described in, for example, EP-A-183 492 (cf. p.13, compound XV) and Haapalinna, A. et al., *Naunyn-Schmiedeberg's Arch. Pharmacol.* **356** (1997) 570-582. U.S. Patent No. 5,902,807 describes compounds that are selective antagonists for the alpha2C subtype and may be used in the treatment of mental illness, e.g. mental disturbance induced by stress. Such compounds include, for example, MK-912 and BAM-1303. Furthermore, WO-A-99 28300 discloses substituted imidazole derivatives having agonist-like activity for alpha2B- or 2B/2C-adrenoceptors. In addition, WO 01/64645 relates to derivatives of quinoline useful as alpha2 antagonists, as well as to selective alpha2C antagonist agents. The disclosures of all documents cited above in this paragraph are incorporated by reference herein.

Several arylquinolizine derivatives and related compounds have been described in the literature, some of which possess valuable pharmaceutical effects. For example, U.S. Patents No. 4,806,545 and 4,044,012 describe 1,1-disubstituted indolo[2,3-*a*]quinolizidines useful as vasodilators and antihypoxic agents. Further, substituted arylquinolizine derivatives, described for example in U.S. Patent No. 4,686,226 possessing alpha2-adrenoceptor antagonistic activity are useful for example as antidepressant, antihypertensive, or antidiabetic agents or platelet aggregation inhibitors. In addition, U.S. Patent No. 3,492,303 relates to indolo[2,3-*a*]quinolizidines useful as central nervous system depressants.

SUMMARY OF THE INVENTION

An object of the present invention is to provide further antagonists of alpha2-adrenoceptors that can be used for the treatment of diseases or conditions of the peripheric or central nervous system where alpha2-antagonists are indicated to be useful. Accordingly, an object of the present invention is to provide further compounds to be used as alpha2 antagonist agents in the treatment of mammals, including humans and animals.

The invention also provides compounds useful as selective alpha2C antagonist agents for the treatment of various disorders or conditions of the central nervous system where alpha2C antagonists are indicated to be useful.

BRIEF DESCRIPTION OF THE DRAWINGS

Figures 1a and b show the results from two separate locomotor activity tests where the locomotor activity of mice was tested after injections of vehicle or amphetamine (amph) (4 micromol/kg). The mice were pre-treated (20 min before amphetamine) either with vehicle, the subtype non-selective alpha2-antagonist atipamezole (1 micromol/kg) or the alpha2C-antagonists, compound K (3 micromol/kg)(Fig a) or compound L (3 micromol/kg)(Fig b). * $p<0.05$, ** $p<0.01$ and *** $p<0.001$ compared to vehicle + amph –group (1-way ANOVA + LSD –test).

Figure 2 shows alpha2-agonist-induced sedation (measured as locomotor inhibition) in mice. The non-selective alpha2-antagonist atipamezole (Ati) antagonised the sedative effects of the alpha2-subtype non-selective agonist, dexmedetomidine (Dex; 50 nmol/kg s.c.), while the alpha2C-selective antagonists did not have significant effects. (veh = vehicle). (***$p<0.001$, compared to Dex + vehicle)

Figure 3 shows the effect of the alpha2C-selective antagonists compound K (3 micromol/kg) and compound L (3 micromol/kg), the non-selective antagonist atipamezole (10 micromol/kg) and the reference antidepressants desipramine (10 micromol/kg) and fluoxetine (10 micromol/kg) in the forced swimming test in rats. All compounds, except atipamezole, increased activity (***$p<0.001$, compared to vehicle).

Figures 4a and 4b show the effect of compounds K and L on the startle reflex and its prepulse inhibition in rats. (Veh = vehicle). Asterisks as in Figure 1; comparisons were performed between PCP (phencyclidine) + vehicle and PCP + compounds K and L.

Figures 5a and 5b show the effect of the non-selective antagonist atipamezole (ati) on the startle reflex and its prepulse inhibition in rats in the prescence of

phencyclidine (PCP); (veh = vehicle). Asterisks as in Figure 1, compared to the vehicle + PCP –group.

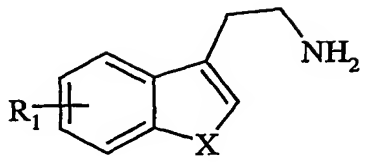
The compounds of formula I and IA, IB, IC, ID and IE, as well as the pharmaceutically acceptable salts and esters thereof, are referred to below as the compounds of the invention, unless otherwise indicated.

The invention includes within its scope all the possible stereoisomers of the compounds, including geometric isomers, e.g. *Z* and *E* isomers (*cis* and *trans* isomers), and optical isomers, e.g. diastereomers and enantiomers. Furthemore, the invention includes in its scope both the individual isomers and any mixtures thereof, e.g. racemic mixtures. The individual isomers may be obtained using the corresponding isomeric forms of the starting material or they may be separated after the preparation of the end compound according to conventional separation methods. For the separation of optical isomers, e.g. enantiomers, from the mixture thereof the conventional resolution methods, e.g. fractional crystallisation, may be used.

Pharmaceutically acceptable salts, e.g. acid addition salts with both organic and inorganic acids are well known in the field of pharmaceuticals. Non-limiting examples of these salts include chlorides, bromides, sulfates, nitrates, phosphates, sulfonates, formates, tartrates, maleates, citrates, benzoates, salicylates and ascorbates. Pharmaceutically acceptable esters, when applicable, may be prepared by known methods using pharmaceutically acceptable acids that are conventional in the field of pharmaceuticals and that retain the pharmacological properties of the free form. Non-limiting examples of those esters include esters of aliphatic or aromatic alcohols, e.g. methyl, ethyl, propyl, isopropyl, butyl, isobutyl, *sec*-butyl and *tert*-butyl esters.

The compounds of the invention can be prepared analogously or according to the methods known in the literature using suitable starting materials. The starting materials of formulae II, III and IV are commercially available or can be prepared via a variety of known synthetic routes known in the literature.

For example, the starting materials used are arylalkylamines of formula (II)

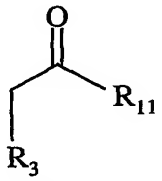


(II)

wherein R1 is as defined above and X is NH, O, CH2 or S.

When X is O, the amines of formula (II) can be prepared, for example, according to the process disclosed in the U.S. Patent Specification No. 4,710,504. When X is CH_2, the compounds of formula (II) can be prepared as described in *J. Med. Chem.* 10 (1967) 856-859. When X is S, the compounds of formula (II) can be prepared by decarboxylation of the corresponding 3-(thianaphten-3-yl)-L-alanine.

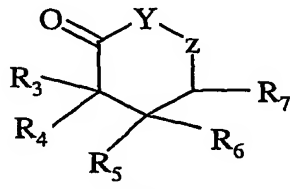
Other starting materials used are compounds of formula (III)



(III)

wherein R_3 is as defined above and R_{11} is OH or halogen.

Furthermore, the starting materials used are compounds of formula (IV)

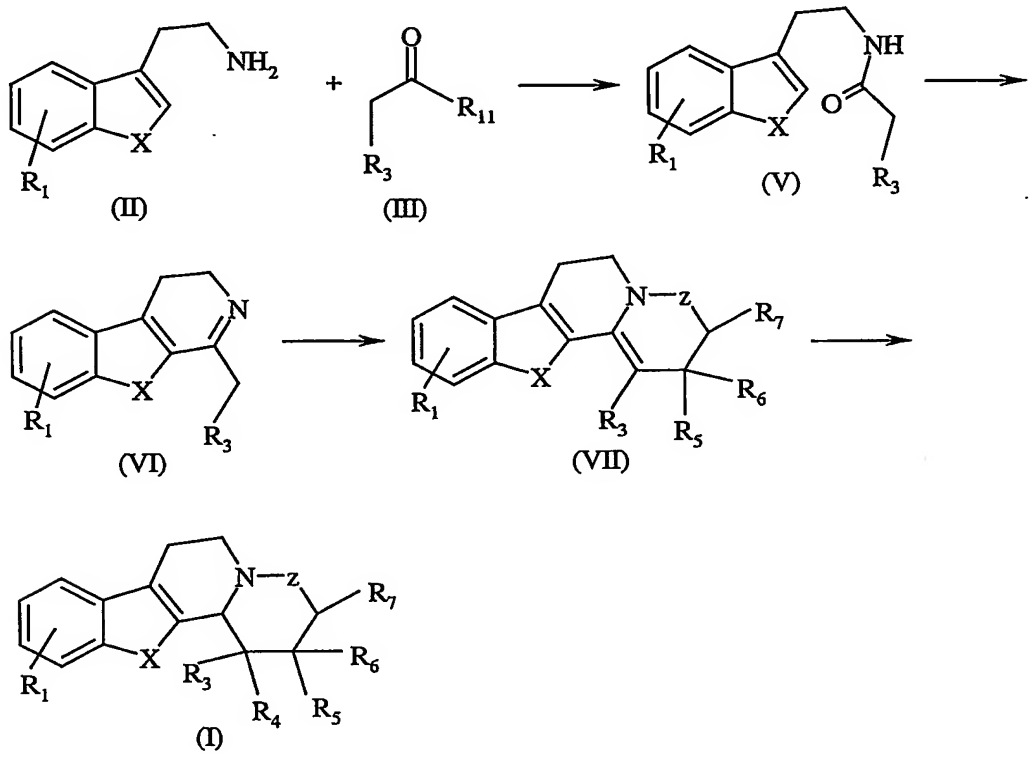


(IV)

wherein R_3-R_7 and Z are as defined above and Y is O or NH. Compounds of formula (IV) can be prepared according to the methods described in *Tetrahedron* 33 (1977) 1803-1808. Analogously, the corresponding acid chlorides can be used instead of lactones (Y=O). When R_3 and R_5 form a ring, compounds of formula (IV) are obtained by the partial reduction of their corresponding anhydrides.

In general, the compounds of formula (I), wherein X is NH, O or S, can be prepared e.g. analogously or according to the following reaction scheme 1:

Scheme 1



wherein R_1, R_3-R_7 and Z are as defined above.

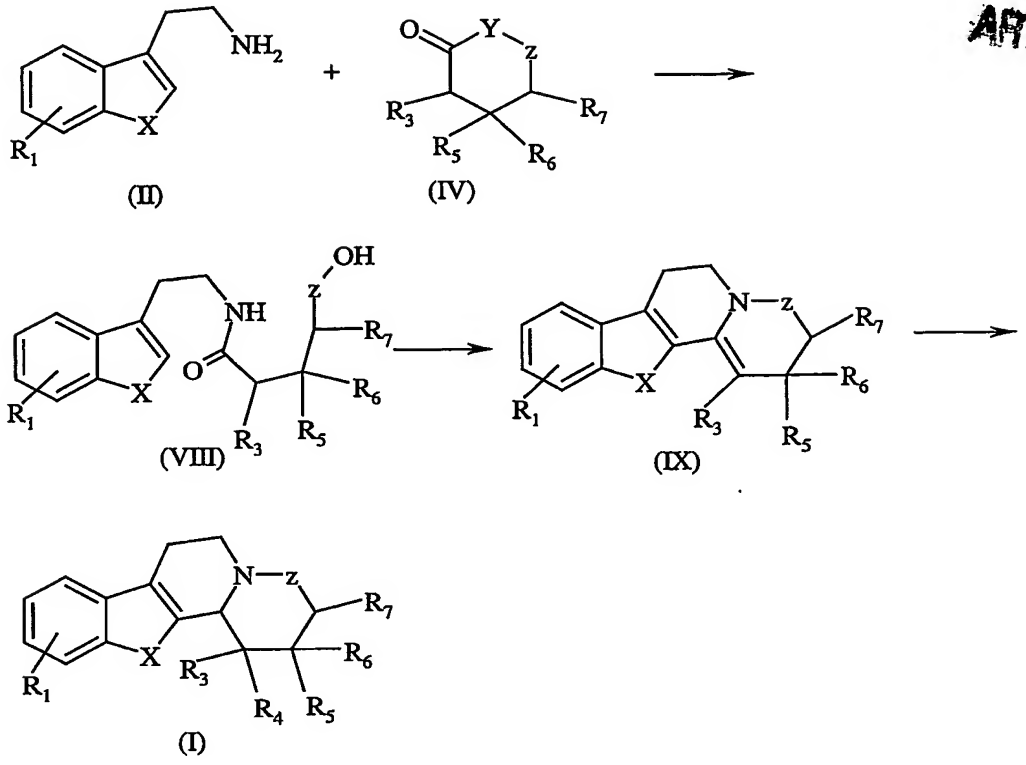
According to the reaction route of scheme I, alkylation of amines (II) with compounds of formula (III) gives amides (V) which are converted into enamines (VII) *via* beta carbolines (V) by Bischler-Napieralski reaction followed by ring D formation by allowing compounds of formula (VI) to react with 1,3-dihaloalkanes under basic conditions as described in *Gazz. Chim. Ital.* 111 (1981) 257-267. In the last step, compounds of formula (I) are obtained

1) by oxidation of enamines (VII) using potassium iodide, iodide and air or

2) by reaction of enamines (VII) with formaldehyde in presence of Hünig base at 60°C.

Another route for preparing compounds of formula (I), wherein X is NR_2, O, CH_2 or S, is illustrated in scheme 2

Scheme 2



(I)

wherein X is NR_2, O, CH_2 or S, R_1-R_7 and Z are as defined above.

In scheme 2 arylalkylamines of formula (II), wherein X is NH, O, CH_2, or S, are reacted with compounds of formula (IV), or the corresponding acid chloride, to give amides (VIII) as described in *Tetrahedron* **33** (1977) 1803-1808. The Bischler-Napieralski cyclization of the intermediates (VIII) leads to enamines (IX) which are converted into compounds of formula (I).

The compounds of formula (I), wherein X is NH, can be alkylated with alkylhalides in the presence of a suitable base at room temperature (*Heterocycles* 27 (1988) 1179-1190) according to following scheme 3:

The functional activities of two compounds (K and L) displaying alpha2C-selectivity in binding experiments were determined as the abilities of the compounds to inhibit the epinephrine-stimulated binding of ^{35}S-GTPγS to G proteins (Jasper, J.R. et al., *Biochem. Pharmacol.* **55(7)** (1998) 1035-44) in membranes of CHO cells stably transfected with the human alpha2-adrenoceptor subtypes. The antagonist potencies of compound K and compound L are presented in the Table 2. The results show that these compounds are selective antagonists for the alpha2C-subtypes.

***In vivo* effects of alpha2C-selective compounds**

It is currently not well-known in the art what effects *in vivo* could be attributed to a selective alpha2C-antagonism. Based on available knowledge and our previous experience, we have selected two different behavioral models, namely *d*-amphetamine –stimulated locomotor activity model and the forced swimming test, in order to demonstrate specific alpha2C-antagonistic effects in the CNS of mice and rats *in vivo*. The selection of these methods is essentially based on published hypotheses on theoretical effects of alpha2C-antagonists; in the lack of suitable ligands, these hypotheses were based on studies employing mice with genetically altered alpha2C-adrenoceptor expression (Scheinin, M. et al., *Life Sci* **68(19-20)** (2001) 2277-85).

EXPERIMENT III: **D-amphetamine stimulated locomotor activity test**

Genetically modified mice having non-functional alpha2C-adrenoceptors (alpha2C-"knockout"; alpha 2C-KO) are more sensitive to the locomotor-enhancing effects of the psychostimulant d-amphetamine and, on the other-hand, over-expression of the alpha2C-adrenoceptor in mice (alpha2C-OE) leads to an opposite effect, i.e. to attenuation of the stimulant effect (Scheinin, M. et al., *Life Sci* **68(19-20)** (2001) 2277-85). Thus, it could be hypothesized that alpha2C-antagonist would potentiate the locomotor effects of d-amphetamine.

The above assumption was tested by administering groups of mice (n = 10-12/dose group) amphetamine (4 micromol/kg s.c.) either alone or together with the alpha2C-antagonists (3 micromol/kg s.c.) of this invention or with the alpha2-subtype non-selective potent alpha2-antagonist (1 micromol/kg s.c.) (Haapalinna, A. et al., *Naunyn-Schmiedeberg's Arch. Pharmacol.* **356** (1997) 570-582), and by subsequently measuring the locomotor activity of mice with an automated infrared photobeam system designed for activity studies (PAS CageRack, SanDiego Instruments, San Diego, CA., USA). As expected, both of the tested alpha2C-selective antagonists increased the activity of mice (Figure 1a+b), as was expected for alpha2C-antagonist. The subtype non-selective alpha2-antagonist also potentiated

the d-amphetamine effect. The tested compounds did not affect the baseline locomotor activity of mice (at doses between 0.1 – 10 mg/kg s.c.).

EXPERIMENT IV: **Antagonism of alpha2-agonist –induced sedation**

One of the prominent effects of non-selective alpha2-agonists in rodents is their ability to cause profound sedation. This effect, measured as locomotor inhibition by the alpha2-agonist dexmedetomidine was not modified in mice with genetically altered alpha2C-expression (Scheinin, M. et al., *Life Sci* **68(19-20)** (2001) 2277-85). On the other hand, alpha2-agonist did not have sedative effect in mice with genetically disrupted alpha2A-adrenoceptor (Hunter, J.C. et al., *British Journal of Pharmacology* **122(7)** (1997) 1339-44). Therefore, since the sedative effect of alpha2-agonists is generally attributed to the alpha2A-adrenoceptor, it is expected that alpha2C-antagonists would not modulate significantly the alpha2-agonist-induced sedation. This assumption was tested in experiment, where dexmedetomidine was administered to mice pre-treated with the alpha2C-antagonists compound K or compound L, or the subtype non-selective antagonist atipamezole (Haapalinna, A. et al., *Naunyn-Schmiedeberg's Arch. Pharmacol.* **356** (1997) 570-582). As expected, the alpha2C-antagonists did not have clear effects, whereas atipamezole effectively antagonised the effect of dexmedetomidine. This result demonstrates the lack of alpha2A-antagonism of the alpha2C-selective compounds of the present invention (Figure 2).

EXPERIMENT V: **Forced swimming test**

Forced swimming test (FST, i.e. Porsolt's test) is generally used in the pharmacological screening of new antidepressants. In this test, antidepressants increase the animals' activity compared to non-treated controls. Alpha2C-KO mice appeared to be more active, and alpha2C-OE mice were less active in FST (U.S. Patent No. 5,902,807 and Scheinin, M. et al., *Life Sci* **68(19-20)** (2001) 2277-85). Therefore, it was tested, whether a selective alfa2C-antagonist would have antidepressant-like activity (e.g. activity-increasing property) in the FST. The figure 3 shows how both of the alpha2C-compounds increased activity in this test as was expected based on studies on transgenic mice (Scheinin, M. et al., *Life Sci* **68(19-20)** (2001) 2277-85) and as reported with recently developed alpha2C-antagonist (WO

01/64645). Also the positive control substances desipramine and fluoxetine (clinically effective antidepressant agents) were active. The subtype non-selective alpha2-antagonist atipamezole did not possess antidepressant-like effect, as expected (WO 01/64645).

EXPERIMENT VI: **Prepulse inhibition of the startle reflex**

Prepulse-inhibition (PPI) of a startle response refers to the reduction in the startle response caused by a low intensity non-startling stimulus (the prepulse) which is presented shortly before the startle stimulus. PPI can be used as an operational measure of sensorimotor gating and appears to be present in all mammals, including rats and humans (Swerdlow, N.R. et al., *The archives of general psychiatry* **51** (1994) 139-154). Normally functioning PPI can be disrupted by psychostimulants, such as d-amphetamine or phencyclidine (PCP), and reversed by clinically effective antipsychotics.

In a previous study, alpha2C-KO mutation was associated with weakened PPI whereas alpha2C-OE demonstrated increased PPI. In other words, the genetically altered alpha2C-expression in mice was associated with changes in PPI in a way suggesting that an alpha2C-antagonist would decrease PPI (Scheinin, M. et al., *Life Sci* **68(19-20)** (2001) 2277-85). This hypothesis was tested with compounds K and L alone and against PCP –disruption of the PPI.

Groups of rats (n =10/group) were administered the alpha2C-antagonists 20 min before, and PCP or vehicle 10 min before measurement of the acoustic startle reactivity and PPI in a test system designed for startle studies (SR-LAB, San Diego Instruments, CA, USA). It was found that the alpha2C-antagonists were able to attenuate the PPI disruption caused by PCP (Figure 3). This was unexpected and opposite to the hypothesis based on transgenic studies. The non-selective alpha2-antagonist atipamezole produced different effects than was observed with the selective alpha2C-antagonists: atipamezole did not enhance PPI, but it increased the startle reflex per se (i.e. startle without prepulses)(Figure 4).

In conclusion, the results presented in this chapter show that those antagonists which are classified as alpha2C-selective according to *in vitro* experiments, appeared to function as alpha2C-selective antagonists also *in vivo* in a manner that was

predicted based on the available knowledge on alpha2C-antagonism. However, the finding that the alpha2C-antagonists did not decrease PPI, as predicted, but on the contrary, increased PPI, could be considered unexpected and this adds the novelty value of the now proposed usefulness of the compounds of the present invention.

The compounds according to the invention may be used to treat any disease or condition wherein alpha-2 antagonists are indicated to be effective. The compounds can also be used to reverse effects induced by alpha-2 agonists. Accordingly, the compounds of the invention may be useful in the treatment of various disorders of the central nervous system (CNS), i.e. different neurological, psychiatric and cognition disorders (such as depression, anxiety disorders, post traumatic stress disorder, schizophrenia, Parkinson's disease and other movement disorders). Furthermore, they may be used in the treatment of various peripheral disorders, e.g. diabetes, orthostatic hypotension, lipolytic disorders (such as obesity), Raynaud's disease or both male and female sexual dysfunctions.

The selective alpha-2C antagonists of the present invention may be used for the treatment of various disorders or conditions of CNS-system where alpha-2C antagonists are indicated to be beneficial, for example, to alleviate the symptoms of various mental disorders propagated by stress, Parkinson's disease, depression, negative symptoms of schizophrenia, attention deficit hyperactivity disorder, post-traumatic stress-disorder, and anxiety disorders.

In addition, due to the novel and previously unpublished findings of the effects of the present alpha2C-antagonists on the PCP –disrupted PPI, the alpha2C-selective compounds can also be used to treat disorders and conditions associated with sensorimotor gating deficits, particularly disorders and conditions wherein the sensorimotor gating deficits results in sensory flooding and cognitive fragmentation causing dysfunction in attention and perception. Such disorders and conditions include, but are not limited to, schizophrenia, obsessive compulsive disorder, Tourette's syndrome, blepharospasm and other focal dystonias, temporal lobe epilepsy with psychosis, drug-induced psychosis (for example, psychosis caused by chronic use of dopaminergic agents) (Braff, D.L. et al., *Psychopharmacology (Berl)* **156(2-3)** (2001) 234-258), Huntington's disease, Parkinson's disease, disorders

caused by fluctuation of the levels of sex hormones (such as premenstrual syndrome), and panic disorder.

Further, the symptoms which are usually associated with above-mentioned disorders or conditions include, but are not limited to, hallucination, delusion, parathymia, agitation, psychotic cognitive impairment (including deficits in thinking and speech), social withdrawal and withdrawal symptoms (including delirium) associated with cessation of cigarette smoking or alcohol or drug abuse. These symptoms may also be seen in animals in exceptional circumstances, for example, during withdrawal from masters or during transportation.

Due to their selectivity of action, the alpha-2C antagonists of the invention have less or no undesirable side-effects attributed to non-selective alpha2-antagonism, such as increases in blood pressure, heart rate, salival secretions, gastrointestinal secretion, anxiety, and startle reactivity per se (Ruffolo, R.R.J. et al., *Annu Rev Pharmacol Toxicol* **32** (1993) 243-279).

The compound of the invention can be administered for example enterally, topically or parenterally by means of any pharmaceutical formulation useful for said administration, and containing at least one active compound of formula I in pharmaceutically acceptable and effective amounts together with pharmaceutically acceptable diluents, carriers, and/or excipients known in the art. The manufacture of such pharmaceutical formulations is well known in the art.

The therapeutic dose to be given to a patient in need of treatment will vary depending on the compound being administered, the species, age and the sex of the subject being treated, the particular condition being treated, as well as the route and method of administration, and are easily determined by person skilled in the art. Accordingly, the typical dosage for oral administration is from 5 μg/kg to 100 mg/kg per day and that for parenteral administration from 0.5 μg/kg to 10 mg/kg for an adult mammal.

The present invention further provides a compound of the invention or an ester or salt thereof for use as alpha-2 antagonist. Furthermore, a method for the treatment of diseases or conditions where alpha-2 antagonists, e.g. alpha-2C antagonists, are indicated to be useful, e.g. a method for the treatment of diseases or

conditions of the central nervous system, is provided. In such a method a therapeutically effective amount of a compound of the invention is administered to a subject in need of such treatment. The use of the compounds of the invention for the manufacture of a medicament to be used for the above indications is also provided.
